Receiver Description Serial Communication Ports Description

The u-blox 5 positioning technology comes with a highly flexible communication interface. It supports both the NMEA and the proprietary UBX protocol. It is truly multi-port and multi-protocol capable. Each protocol (UBX, NMEA) can be assigned to several ports at the same time (multi-port capability) with individual settings (e.g. baud rate, messages enabled, etc.) for each port. It is even possible to assign more than one protocol (e.g. UBX protocol and NMEA at the same time) to a single port (multi-protocol capability), which is particularly useful for debugging purposes.

The UBX and/or NMEA protocol must be activated to get a message on a port using the UBX proprietary message UBX-CFG-PRT, which also allows to change port-specific settings (baud rate, address etc.). See CFG-MSG for a description of the mechanism of enabling and disabling messages.

UART Ports

The receivers feature one or two universal asynchronous receiver/transmitter (<u>UART</u>) ports that can be used to transmit GPS measurements, monitor status information and configure the receiver. The availability of the second port depends on the type of module or chip set (see our online product selector matrix for <u>modules</u> and <u>chip sets</u>).

The serial ports consist of an RX and a TX line. Neither handshaking signals nor hardware flow control signals are available. These serial ports operate in asynchronous mode. The baud rates can be configured individually for each serial port. However, there is no support for setting different baud rates for reception and transmission or for different protocols on the same port.

Possible UART Interface Configurations

Baud Rate	Data Bits	Daritu	Stop Dita
Daud Kale	Data BILS	Parity	Stop Bits
4800	8	none	1
9600	8	none	1
19200	8	none	1
38400	8	none	1
57600	8	none	1
115200	8	none	1

If too much data is being configured for a certain port's bandwidth (e.g. all UBX messages shall be output on a UART port with a baud rate of 9600), the buffer will fill up. Once the buffer's space is exceeded, the receiver will deactivate messages automatically.

Please note that for protocols such as NMEA or UBX, it does not make sense to change the default values of word length (data bits) since these properties are defined by the protocol, not by the electrical interface.

See CFG-PRT for UART for a description on the contents of the UART port configuration message.

USB Port

The receivers feature one USB (<u>Universal Serial Bus</u>) port, depending on the type of module or chip set (see our online product selector matrix for <u>modules</u> and <u>chip sets</u>). This port can be used not only for communication purposes, but also to power the GPS receiver.

The USB interface supports two different power modes:

NMEA, UBX Protocol Specification, u-blox 5 GNSS Receiver
GPS.G5-X-07036-D
Public Release

- In the *Self Powered Mode* the receiver is powered by its own power supply. **VDDUSB** is used to detect the availability of the USB port, i.e. whether the the receiver is connected to a USB host.
- In the *Bus Powered Mode* the device is powered by the USB bus, therefore no additional power supply is needed. The default maximum current that can be drawn by the receiver is 120mA in that mode. See CFG-USB for a description on how to change this maximum. Configuring the Bus Powered Mode implies that the device enters a low power state with disabled GPS functionality when the host suspends the device, e.g. when the host is put into stand-by mode.

The voltage range for **VDDUSB** is specified from 3.0V to 3.6V, which differs slightly from the specification for VCC

DDC Port

A DDC Bus (<u>Display Data Channel</u>) is implemented, which is a 2-wire communication interface compatible with the I2C standard (<u>Inter-Integrated Circuit</u>). Its availability is depending on the type of module or chip set (see our online product selector matrix for <u>modules</u> and <u>chip sets</u>).

In contrast to all other interfaces, the DDC is not able to communicate in full-duplex mode, i.e. TX and RX are mutually exclusive. u-blox 5 acts as a slave in the communication setup, therefore it cannot initiate data transfers on its own. The master provides the data clock, therefore master and slave don't need to be configured to use the same baud rate. Moreover, a baud rate setting is not applicable for the slave.

The baud rate clock provided by the master must not exceed 100kHz

The receiver's DDC address is set to 0x42 by default. This address can be changed by setting the mode field in CFG-PRT for DDC accordingly.

As the receiver will be run in slave mode and the physical layer lacks a handshake mechanism to inform the master about data availability, a layer has been inserted between the physical layer and the UBX and NMEA layer. The DDC implements a simple streaming interface that allows the constant polling of data, discarding everything that is not parseable. This means that the receiver returns 0xFF if no data is available.

If no data is polled for an extended period, the receiver temporarily stops writing data to the output buffer to prevent overflowing.

Read Access

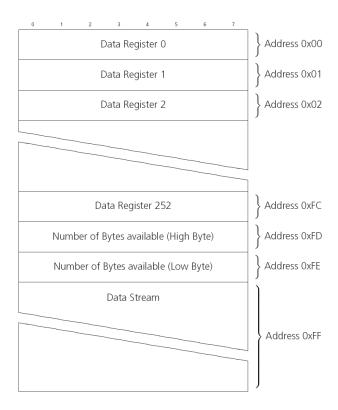

To allow both polled access to the full message stream and quick access to the key data, the register layout depicted in Figure *DDC Register Layout* is provided. The data registers 0 to 252, at addresses 0x00 to 0xFC, each 1 byte in size, contain information to be defined at a later point in time. At addresses 0xFD and 0xFE, the currently available number of bytes in the message stream can be read. At address 0xFF, the message stream is located. Subsequent reads from 0xFF return the messages in the transmit buffer, byte by byte. If the number of bytes read exceeds the number of bytes indicated, the payload is padded using the value 0xFF.

The registers 0x00 to 0xFC will be defined in a later firmware release. Do not use them, as they don't provide any meaningful data!

DDC Register Layout

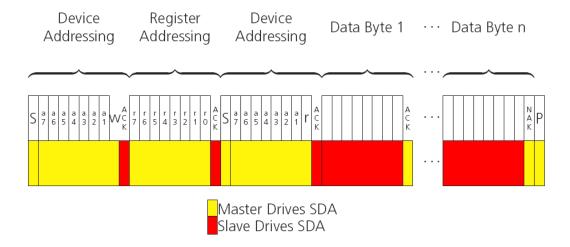

Random Read Access

Random read operations allow the master to access any register in a random manner. To perform this type of read operation, first the register address to read from must be written to the receiver (see Figure DDC Random Read Access). Following the start condition from the master, the 7-bit device address including the RW bit (which is a logic low for write access) are clocked onto the bus by the master transmitter. The receiver answers with an acknowledge (logic low) to indicate that it is responsible for the given address. Next, the 8-bit address of the register to be read must be written to the bus. Following the receiver's acknowledge, the master again triggers a start condition and writes the device address, but this time the RW bit is a logic high to initiate the read access. Now, the master can read 1 to N bytes from the receiver, generating a not-acknowledge and a stop condition after the last byte being read. After every byte being read, the internal address counter is incremented by one, saturating at 0xFF. This saturation means, that, after having read all registers coming after the initially set register address, the raw message stream can be read.

DDC Random Read Access

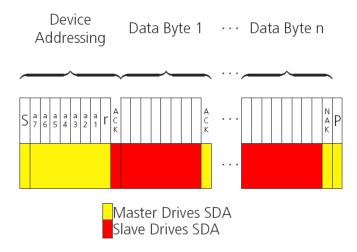

Current Address Read

The receiver contains an address counter that maintains the address of the last register accessed, internally incremented by one. Therefore, if the previous read access was to address n (n is any legal address), the next current address read operation would access data from address n+1 (see Figure DDC Current Address Read Access). Upon receipt of the device address with the RW bit set to one, the receiver issues an acknowledge and the master can read 1 to n bytes from the receiver, generating a not-acknowledge and a stop condition after the last byte being read.

To allow direct access to streaming data, the internal address counter is initialized to 0xFF, meaning that current address reads without a preceding random read access return the raw message stream. The address counter can be set to another address at any point in time using a random read access.

DDC Current Address Read Access

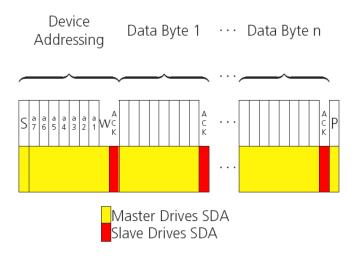

Write Access

The receiver does not provide any write access except for writing UBX messages (and NMEA messages) to the receiver, such as configuration or aiding data. Therefore, the register set mentioned in section Read Access is not writable. Following the start condition from the master, the 7-bit device address including the RW bit (which

is a logic low for write access) are clocked onto the bus by the master transmitter. The receiver answers with an acknowledge (logic low) to indicate that it is responsible for the given address. Now, the master can write 2 to π bytes to the receiver, generating stop condition after the last byte being written. The number of bytes must exceed 2 to properly distinguish from the write access to set the address counter in random read accesses.

DDC Write Access

SPI Port

An SPI Bus (<u>Serial Peripheral Interface</u> is provided, depending on the type of module or chip set (see our online product selector matrix for <u>modules</u> and <u>chip sets</u>). The SPI is a 3-wire synchronous communication interface; In contrast to UART the master provides a clock, meaning that master and slave don't need to be configured to use the same baud rate. Moreover, a baud rate setting is not applicable for the slave. SPI modes 0-3 are implemented and can be configured using the field mode.spiMode in CFG-PRT for SPI (default is SPI mode 0).

The baud rate clock provided by the master must not exceed 250kHz

Read Access

As the register mode is not implemented for the SPI port, only the UBX/NMEA message stream is provided. This stream is accessed using the Back-To-Back Read and Write Access (see section Back-To-Back Read and Write Access). When no data is available to be written to the receiver, MOSI should be held logic high, i.e. all bytes written to the receiver are set to OxFF.

In order to prevent the receiver from being busy parsing the incoming data, the parsing process is stopped after 20 subsequent bytes containing 0xFF. The parsing process gets re-enabled with the first byte not equal to 0xFF. The number of bytes to wait for deactivation (20 by default) can be adjusted using the field mode.ffCnt in CFG-PRT for SPI.

If the receiver has no more data to send, it pulls MISO to logic high, i.e. all bytes transmitted are set to 0xFF. This means that the master should ignore all 0xFF which are not part of a message. It can resume data processing as soon as the first byte not equalling 0xFF is received.

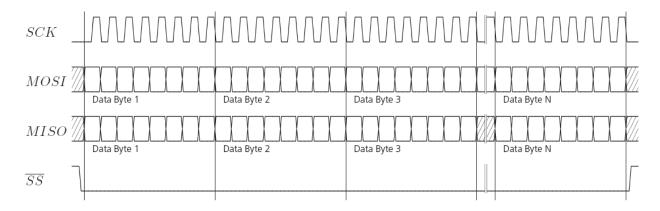

Page 8

Back-To-Back Read and Write Access

The receiver does not provide any write access except for writing UBX messages (and eventually NMEA messages) to the receiver, such as configuration or aiding data. For every byte written to the receiver, a byte must be read from the receiver; the master writes to MOSI and, at the same time, it reads from MISO. The data on MISO represents the results from a current address read, returning 0xFF when no more data is available.

SPI Back-To-Back Read/Write Access

How to change between protocols

Reconfiguring a port from one protocol to another is a two-step process. First of all, the preferred protocol(s) needs to be enabled to a port using CFG-PRT. One port can handle several protocols at the same time (e.g. NMEA and UBX). By default, all ports are configured for UBX and NMEA protocol so in most cases, it's not necessary to change the port settings at all. Port settings can be viewed and changed using the CFG-PRT messages.

As a second step, activate certain messages on each port using CFG-MSG.

Despite the fact that concatenation of several configurations is still possible on receivers before u-blox 5, the use of this feature is discouraged as it won't work on u-blox 5. u-blox 5 has 6 I/O ports, so backwards compatibility is dropped at this point.

This message can be used to initiate receiver restart scenarios, optionally erasing information the receiver has acquired.

Typically, in GPS receivers, one distinguishes between Cold-, Warm- and Hotstarts, depending on the type of valid information the receiver has at the time of the restart.

- Coldstart In this startup mode, the receiver has **no** a-priori information on last position, time, velocity, frequency etc. Therefore, the receiver has to search the full time- and frequency space, and also all possible satellite numbers. If a satellite signal is found, it is being tracked to decode ephemeris (18-36 seconds under strong signal conditions), whereas the other channels continue to search satellites. Once there are sufficient number of satellites with valid ephemeris, the receiver can calculate position- and velocity data. Please note that some competitors call this startup mode Factory Startup.
- Warmstart In warmstart mode, the receiver has approximate information of time, position, and coarse data on Satellite positions (Almanac). In this mode, after power-up, the receiver basically needs to download ephemeris until it can calculate position- and velocity data. As the ephemeris data usually is outdated after 4

hours, the receiver will typically start with a warmstart if it was powered down for more than that amount of time. For this scenario, several augmentations exist. See the sections on AssistNOW online and offline.

• **Hotstart** In Hotstart, the receiver was powered down only for a short time (4 hours or less), so that its ephemeris is still valid. Since the receiver doesn't need to download ephemeris again, this is the fastest startup method.

In the UBX-CFG-RST message, one can force the receiver to reset and clear data, in order to see the effects of maintaining/losing such a-priori data between restarts. For that, the CFG-RST message offers the navBbrMask field, where Hot-, Warm- and Coldstarts can be initiated, and also other combinations thereof.

The Reset Type can also be specified. This is not GPS-related, but the way the software restarts the system.

- **Hardware Reset** uses the on-chip Watchdog, in order to electrically reset the chip. This is an immediate, asynchronous reset. No Stop events are generated. This is equivalent to pulling the Reset signal on the receiver
- **Controlled Software Reset** terminates all running processes in an orderly manner and, once the system is idle, restarts operation, reloads its configuration and starts to acquire and track GPS satellites
- **Controlled Software Reset (GPS only)** only restarts the GPS tasks, without reinitializing the full system or reloading any stored configuration.
- **Controlled GPS Stop** stops all GPS tasks. The receiver will not be restarted, but will stop any GPS related processing.
- Controlled GPS Start starts all GPS tasks.

Geodetic Datum

Predefined Datum

The following, predefined Datum Values are available and can be configured using UBX message CFG-DAT. For the ellipsoid parameters, see ellipsoid section below. For the rotation and scale parameters, see rotation and scale section below.

The receiver defaults to WGS84 datum

Geodetic Datum Defined in Firmware

Timepulse Configuration

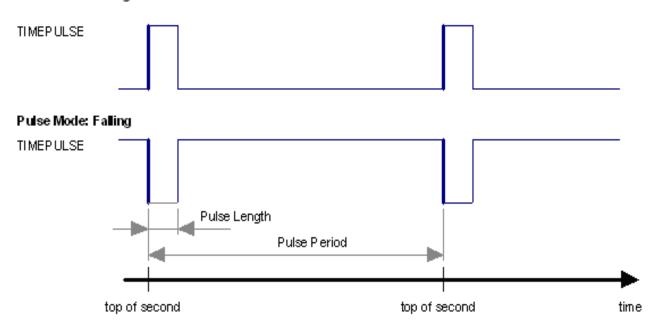

The receiver provides a hardware-synchronized timepulse (Pin 29) with a time pulse (TP) period of 1 ms to 60 s. The polarity (rising or falling edge) and the pulse duration can be configured. Use the UBX proprietary message CFG-TP to change the timepulse settings. The UBX-TIM-TP message provides the time information for the next timepulse, time source and a quantization error.

The CFG-TP message comprises the following parameters defining the hardware-synchronized timepulse:

- **pulse interval** time interval between timepulses
- pulse length duration of the timepulse (time period between rising and falling edge)
- **pulse mode** if not disabled the synchronization of timepulse can be configured to be done on rising or falling edge
- **time reference** the reference time source (time base) used for timepulse synchronization and timepulse time given in TIM-TP output message
- **synchronization mode** the timepulse can be configured to be always synchronized and will be available only in this case. If the timepulse is allowed to be asynchronized it will be available at any time even when the time is not valid.
- antenna cable delay the signal delay due to the cable between antenna and receiver
- **RF group delay** delay of the signal in the RF module of the u-blox 5 receiver (hard coded)
- **user delay** the cable delay from u-blox 5 receiver to the user device plus signal delay of any user application

Pulse Mode: Rising

Notes:

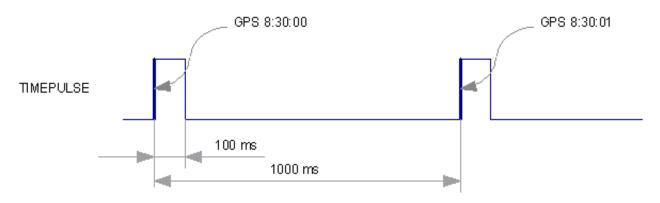

- The pulse period must be an integer multiple of 60 seconds.
- The maximum pulse length can't exceed the pulse period minus 1 microsecond.
- A timepulse is only output when the receiver has determined the time with sufficent accuracy and reliability.

Recommendations:

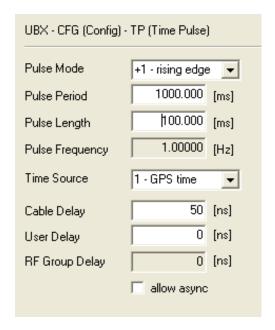

- When using the timepulse for a timing application it is recommended to calibrate the RF signal delay against a reference-timing source.
- In order to get the best timing accuracy with the antenna, a fixed *accurate* position is needed. Once the receiver is in timing mode, the dynamic model does not influence the timing accuracy.

Example:

The example shows the 1PPS timepulse signal generated according the specific parameters of the CFG-TP message.

Receiver Configuration

Configuration Concept

u-blox 5 positioning technology is fully configurable with UBX protocol configuration messages (message class UBX-CFG). The configuration used by the u-blox 5 GPS core during normal operation is termed "Current Configuration". The Current Configuration can be changed during normal operation by sending any UBX-CFG-XXX message to the receiver over an I/O port. The receiver will change its Current Configuration immediately after receiving the configuration message. The u-blox 5 GPS core always uses only the Current Configuration.

Unless the Current Configuration is made permanent by using UBX-CFG-CFG as described below, the Current Configuration will be lost in case of (see message CFG-RST)

- a power cycle
- a hardware reset
- a (complete) controlled software reset

The Current Configuration can be made permanent (stored in a non-volatile memory) by saving it to the "Permanent Configuration". This is done by sending a UBX-CFG-CFG message with an appropriate **saveMask** (UBX-CFG-CFG/save).

The Permanent Configurations are copied to the Current Configuration after start-up or when a UBX-CFG-CFG message with an appropriate **loadMask** (UBX-CFG-CFG/load) is sent to the receiver.

The Permanent Configuration can be restored to the receiver's Default Configuration by sending a UBX-CFG-CFG message with an appropriate **clearMask** (UBX-CFG-CFG/clear) to the receiver.

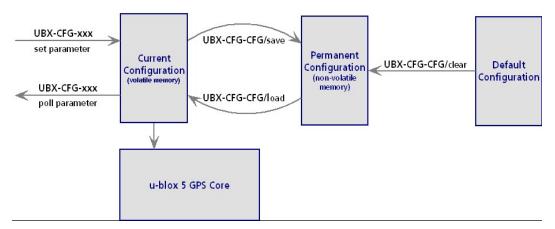

This only replaces the Permanent Configuration, not the Current Configuration. To make the receiver operate with the Default Configuration which was restored to the Permanent Configuration, a UBX-CFG-CFG/load command must be sent or the receiver must be reset.

The mentioned masks (saveMask, loadMask, clearMask) are 4 byte bit fields . Every bit represents one configuration sub-section. These sub-sections are defined in section "Organization of the Configuration

Sections"). All three masks are part of every UBX-CFG-CFG message. Save, load and clear commands can be combined in the same message. Order of execution is save, load, clear.

The following diagram illustrates the process:

Organization of the Configuration Sections

The configuration is divided into several sub-sections. Each of these sub-sections corresponds to one or several UBX-CFG-XXX messages. The sub-section numbers in the following table correspond to the bit position in the masks mentioned above.

Configuration sub-sections

sub-section	CFG messages	Description
0	UBX-CFG-PRT	Port and USB settings
	UBX-CFG-USB	
1	UBX-CFG-MSG	Message settings (enable/disable, update rate)
2	UBX-CFG-INF	Information output settings (Errors, Warnings, Notice, Test etc.)
3	UBX-CFG-NAV5	Navigation Parameter, Receiver Datum, Measurement and Navigation Rate
	UBX-CFG-DAT	setting, Timemode settings, SBAS settings, NMEA protocol settings
	UBX-CFG-RATE	
	UBX-CFG-SBAS	
	UBX-CFG-NMEA	
	UBX-CFG-TMODE	
4	UBX-CFG-TP	Timepulse Settings
5	N/A	Reserved for future low power modes
6-9	N/A	Reserved for EKF (Dead Reckoning) Receivers
10	UBX-CFG-ANT	Antenna configuration
11-31	N/A	Reserved

Permanent Configuration Storage Media

The Current Configuration is stored in the receiver's volatile RAM. Hence, any changes made to the Current Configuration without saving will be lost in the events listed in the section above. By using UBX-CFG-CFG/save, the selected configuration sub-sections are saved to all non-volatile memories available:

- On-chip BBR (battery backup RAM). In order for the BBR to work, a backup battery must be applied to the receiver.
- External FLASH memory, where available.

• External EEPROM (Electrically Erasable Programmable Read-Only Memory), where available via DDC (I2C compatible).

Receiver Default Configuration

Permanent Configurations can be reset to Default Configurations through a UBX-CFG-CFG/clear message. The receiver's Default Configuration is determined at system startup. The Default Configuration depends on various information such as system clock frequency and others. The receiver searches for this information in various places (memories and configuration pins). Refer to the receiver's data sheet for details.

Power modi for search engine

The receiver determines how and if to search for satellites depending on power configuration (low-level config), number of satellites tracked and if a valid position could be calculated.

Max. Performance mode

In max. performance mode, the receiver searches for all satellites which are currently not tracked on a channel and not invisible (as far as information from satellite pre-positioning is available). If no information is available, the unknown and known-visible satellites are be searched continuously.

Eco mode

In eco mode, if no valid fix could be calculated before, the receiver searches for all satellites with the search engine as then no assumptions about visibility can be made. After a fix could be calculated, the receiver no more uses the search engine to search for satellites without pre-positioning information. Pre-positioning information is available for satellites if orbits for this special SV, and position and time are known at the receiver. If a confirmed position and time are determined and a sufficient number (more or equal to 4) of satellites are tracked, the search engine is completely powered off.

Remark that even if the search engine is powered off, satellites can be found and tracked due to pre-positioning information (slightly slower) or without information at all (significantly slower).

Additionally to these strategic changes, the search engine does not use all resources available in the search engine, saving computational load and therefore reducing power consumption, but increasing mean time to find the satellites.

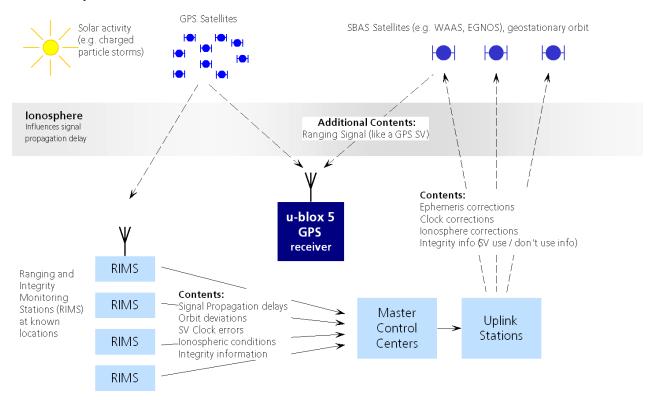

SBAS Configuration Settings Description

SBAS (Satellite Based Augmentation Systems)

SBAS (Satellite Based Augmentation System) is an augmentation technology for GPS, which calculates GPS integrity and correction data with RIMS (Ranging and Integrity Monitoring Stations) on the ground and uses geostationary satellites (GEOs) to broadcast GPS integrity and correction data to GPS users. The correction data is transmitted on the GPS L1 frequency (1575.42 MHz), and therefore no additional receiver is required to make use of the correction- and integrity data.

SBAS Principle

There are several compatible SBAS systems available or in development all around the world:

- WAAS (Wide Area Augmentation System) for North America has been in operation since 2003.
- MSAS (Multi-Functional Satellite Augmentation System) for Asia has been in operation since 2007.
- EGNOS (European Geostationary Navigation Overlay Service) is in test mode ESTB (EGNOS satellite test bed).
 EGNOS has passed the ORR (Operational Readiness Review) in Q2/2005. Full operation of EGNOS is planned for 2008.
- GAGAN (GPS Aided Geo Augmented Navigation), developed by the Indian government is in test mode and expected to be operational by 2010.

Other systems are planned for Canada (CSAS), Africa (EGNOS) and South America.

SBAS support allows u-blox 5 technology to take full advantage of the augmentation systems that are currently available (WAAS, EGNOS, MSAS), as well as those being tested and planned (such as GAGAN).

With SBAS enabled the user benefits from additional satellites for ranging (navigation). u-blox 5 technology uses the available SBAS Satellites for navigation just like GPS satellites, if the SBAS satellites offer this service.

To improve position accuracy SBAS uses different types of correction data:

- Fast Corrections for short-term disturbances in GPS signals (due to clock problems, etc).
- Long-term corrections for GPS clock problems, broadcast orbit errors etc.
- **lonosphere corrections** for lonosphere activity

Another benefit is the use of GPS integrity information. In this way SBAS Control stations can 'disable' usage of GPS satellites in case of major GPS satellite problems within a 6 second alarm time. If integrity monitoring is enabled, u-blox 5 GPS technology will only use satellites, for which integrity information is available.

For more information on SBAS and associated services please refer to

- RTCA/DO-229C (MOPS). Available from www.rtca.org
- gps.faa.gov for information on WAAS and the NSTB

- www.esa.int for information on EGNOS and the ESTB
- <u>www.essp.be</u> for information about European Satellite Services Provider EEIG is the EGNOS operations manager.
- www.kasc.go.jp for information on MSAS

SBAS GEO PRN Numbers

GEO identification	Stationed over	GPS PRN	SBAS Provider
Inmarsat AOR-E	Eastern Africa	120	EGNOS
Inmarsat AOR-W	Western Africa	122	WAAS
ESA Artemis	Africa (Congo)	124	EGNOS
Inmarsat IND-W	Africa (Congo)	126	EGNOS
Insat-NAV	(tbd)	127	GAGAN
Insat-NAV	(tbd)	128	GAGAN
MTSAT-1R (or MTSAT-2)	Pacific	129	MSAS
Inmarsat IOR	Indian Ocean	131	EGNOS
Inmarsat POR	Pacific	134	WAAS
PanAmSat Galaxy XV	133° West	135	WAAS
MTSAT-2 (or MTSAT-1R)	(tbd)	137	MSAS
Telesat Anik F1R	107° West	138	WAAS

SBAS Features

This u-blox 5 SBAS implementation is, in accordance with standard RTCA/DO-229C, a class Beta-1 equipment. All timeouts etc. are chosen for the En Route Case. Do not use this equipment under any circumstances for safety of life applications!

u-blox 5 is capable of receiving multiple SBAS satellites in parallel, even from different SBAS systems (WAAS, EGNOS, MSAS, etc.). They can be tracked and used for navigation simultaneously. At least three SBAS satellites can be tracked in parallel. Every SBAS satellite tracked utilizes one vacant GPS receiver tracking channel. Only the number of receiver channels limits the total number of satellites used. Each SBAS satellite, which broadcasts ephemeris or almanac information, can be used for navigation, just like a normal GPS satellite.

For receiving correction data, the u-blox 5 GPS receiver automatically chooses the best SBAS satellite as its primary source. It will select only one since the information received from other SBAS GEOs is redundant and/or could be inconsistent. The selection strategy is determined by the proximity of the GEOs, the services offered by the GEO, the configuration of the receiver (Testmode allowed/disallowed, Integrity enabled/disabled) and the signal link quality to the GEO.

In case corrections are available from the chosen GEO and used in the navigation calculation, the DGPS flag is set in the receiver's output protocol messages (see NAV-SOL, NAV-STATUS, NAV-SVINFO, NMEA Position Fix Flags description).

The most important SBAS feature for accuracy improvement is lonosphere correction. The measured data from RIMS stations of a region are combined to a TEC (Total Electron Content) Map. This map is transferred to the GPS devices via the GEOs to allow a correction of the ionosphere error on each received satellite.

Supported SBAS messages

Message Type	Message Content	Used from GEO
0(0/2)	Test Mode	All
1	PRN Mask Assignment	Primary
2, 3, 4, 5	Fast Corrections	Primary
6	Integrity	Primary

NMEA, UBX Protocol Specification, u-blox 5 GNSS Receiver GPS.G5-X-07036-D Public Release

Supported SBAS messages continued

Message Type	Message Content	Used from GEO
7	Fast Correction Degradation	Primary
9	GEO Navigation (Ephemeris)	All
10	Degradation	Primary
12	Time Offset	Primary
17	GEO Almanacs	All
18	Ionosphere Grid Point Assignment	Primary
24	Mixed Fast / Long term Corrections	Primary
25	Long term Corrections	Primary
26	Ionosphere Delays	Primary

As each GEO services a specific region, the correction signal is only useful within that region. Therefore, mission planning is crucial to determine the best possible configuration. The different stages (Testmode vs. Operational) of the various SBAS systems further complicate this task. The following examples show possible scenarios:

Example 1: SBAS Receiver in North America

At the time of writing, the WAAS system is in operational stage, whereas the EGNOS system is still in test mode (ESTB). Therefore, and especially in the eastern parts of the US, care must be taken in order not to have EGNOS satellites taking preference over WAAS satellites. This can be achieved by disallowing Test Mode use (this inhibits EGNOS satellites from being used as a correction data source), but keeping the PRN Mask to have all SBAS GEOs enabled (which allows EGNOS GEOs to be used for navigation).

Example 2: SBAS Receiver in Europe

At the time of writing, the EGNOS system is still in test mode. To try out EGNOS operation, Testmode usage must be enabled. Since the WAAS GEO #122 can be received in the western parts of Europe, but since this GEO does not carry correction data for the European continent, the GEOs from all but the EGNOS system should be disallowed, using the PRN Mask. It is important to understand that while EGNOS is in test mode, anything can happen to the EGNOS signals, such as sudden interruption of service or broadcast of invalid or inconsistent data.

The u-blox 5 GPS receiver always makes use of the best available SBAS correction data.

SBAS Configuration

To configure the SBAS functionalities use the UBX proprietary message UBX-CFG-SBAS (SBAS Configuration).

SBAS Configuration parameters

Parameter	Description
Mode - SBAS Subsystem	Enables or disables the SBAS subsystem
Mode - Allow test mode usage	Allow / Disallow SBAS usage from satellites in Test Mode (Message 0)
Services/Usage - Ranging	Use the SBAS satellites for navigation
Services/Usage - Apply SBAS	Combined enable/disable switch for Fast-, Long-Term and Ionosphere
correction data	Corrections
Services/Usage - Apply integrity	Use integrity data
information	

SBAS Configuration parameters continued

Parameter	Description
Number of tracking channels	Sets how many channels are reserved for SBAS tracking (if that many
	SBAS signals were acquired). E.g., if this is set to three and five SBAS
	SVs are acquired, only three of them will prioritized over available GPS
	signals.
PRN Mask	Allows to selectively enable/disable SBAS satellite. With this parameter,
	for example, one can restrict SBAS usage to WAAS-only

By default SBAS is enabled with three prioritized SBAS channels and it will use any received SBAS satellites (except for those in test mode) for navigation, ionosphere parameters and corrections.

NMEA Protocol Configuration

The NMEA protocol on u-blox receivers can be configured to the need of customer applications using CFG-NMEA. As default all invalid positions out of the defined accuracy range are not reported.

There are two NMEA standards supported. The default NMEA protocol version is 2.3. Alternatively also Specification version 2.1 can be enabled (for details on how this affect the output refer to section Position Fix Flags in NMEA Mode).

NMEA filtering flags

Parameter	Description
Position filtering	If disabled, invalid or old position output is being communicated, but the valid flag
	indicates that the data is not current.
Masked position	If disabled, Masked position data is still being output, but the valid flag will indicate that
filtering	the defined accuracy range has been exceeded.
Time filtering	If disabled, the receiver's best knowledge of time is output, even though it might be
	wrong.
Date filtering	If disabled, the receiver's best knowledge of date is output, even though it might be
	wrong.
SBAS filtering	If enabled, SBAS satellites are reported according to the NMEA standard.
Track filtering	If disabled, an unfiltered course over ground (COG) output is being output.

NMEA flags

Parameter	Description
Compatibility Mode	Some NMEA applications only work with a fixed number of digits behind the decimal
	comma. Therefore u-blox receivers offer a compatibility mode to communicate with the
	most popular map applications.
Consideration Mode	u-blox receivers use a sophisticated signal quality detection scheme, in order to produce
	the best possible position output. This algorithm considers all SV measurements, and
	eventually decides to only use a subset thereof, if it improves the overall position
	accuracy. If Consideration mode is enabled, all Satellites, which were considered for
	navigation, are being communicated as being used for the position determination. If
	Consideration Mode is disabled, only those satellites are marked as being used, which
	after the consideration step remained in the position output.

Time Mode Configuration

Introduction

Time Mode is a special stationary GPS receiver mode where the position of the receiver is known and fixed and only the time is calculated using all available satellites. This mode allows for maximum time accuracy as well as for single-SV solutions.

Fixed Position

In order to use the *Time Mode*, the receiver's position must be known as exactly as possible. Either the user already knows and enters the position, or it is determined using a Survey-in. Errors in the fixed position will translate into time errors depending on the satellite constellation. Using the TDOP value (see UBX-NAV-DOP) and assuming a symmetrical 3D position error, the expected time error can be estimated as

```
time error = tdop * position error
```

As a rule of thumb the position should be known better than 1m for a time accuracy on the order of nanoseconds. If only microseconds accuracy is required, a position accuracy of roughly 300m is sufficient.

Survey-in

Survey-in is the procedure of determining a stationary receiver's position prior to using *Time Mode* by averaging. The current implementation builds a weighted mean of all valid 3D position solutions. Two stop criteria can be specified:

- The **minimum observation time** defines a minimum amount of observation time regardless of the actual number of valid fixes that were used for the position calculation. Reasonable values range from one day for high accuracy requirements to a few minutes for coarse position determination.
- The **required 3D position standard deviation** forces the calculated position to be of at least the given accuracy. As the position error translates into a time error when using *Time Mode* (see above), one should carefully evaluate the time accuracy requirements and the choose an appropriate position accuracy requirement.

Survey-In ends, when **both** requirements are met. After Survey-In has finished successfully, the receiver will automatically enter fixed position *Time Mode*. The Survey-In status can queried using the UBX-TIM-SVIN message.

Navigation Configuration Settings Description

Platform settings

u-blox 5 positioning technology supports different dynamic platform models to adjust the navigation engine to the expected environment. These platform settings can be changed dynamically without doing a power cycle or reset. It allows a better interpretation of the measurements and hence provides a more accurate position output. Setting the receiver to an unsuitable platform model for the application environment may reduce the receiver performance and position accuracy significantly.

Dynamic Platform Model

Platform	Description
Portable	Default setting. Applications with low accelerations, as any portable devices. Suitable for
	most situations.
Stationary	Used in timing applications (antenna must be stationary) or other stationary applications.
	Velocity is constrained to 0 m/s. Zero dynamics assumed.
Pedestrian	Applications with low accelerations and low speed, as a pedestrian would move. Assuming
	low accelerations.
Automotive	Used for applications that can be compared with the dynamics of a passenger car.
	Assuming low vertical acceleration.
At sea	Recommended for applications at sea, with zero vertical velocity. Assuming zero vertical
	velocity.
Airborne <1g	Used for applications that have to handle a higher dynamic range than a car and higher
	vertical accelerations. No 2D position fixes supported.
Airborne <2g	Recommended for typical airborne environment. No 2D position fixes supported.
Airborne <4g	Only recommended for an extreme dynamic environment. No 2D position fixes supported.

Dynamic platforms designed for high acceleration systems (e.g. airborne <2g) may result in a greater standard deviation in the reported position.

Navigation Input Filters

The navigation input filters mask the input data of the navigation engine.

These settings are already optimized. It is not recommended that changes to any parameters be made unless advised by u-blox support engineers.

Navigation Input Filter parameters

Parameter	Description
fixMode	By default, the receiver calculates a 3D position fix if possible but reverts to a 2D position if
	necessary (Auto 2D/3D). It is possible to force the receiver to permanently calculate 2D (2D
	only) or 3D (3D only) positions.
fixedAlt and	The fixed altitude is used if fixMode is set to 2D only. A variance greater than zero must be
fixedAltVar	supplied as well.
minElev	Minimum elevation of a satellite above the horizon in order to be used in the navigation
	solution. Low elevation satellites may provide degraded accuracy, because of the long
	signal path through the atmosphere.
drLimit	Dead Reckoning limit: The time during which the receiver provides an extrapolated
	solution. After the DR timeout has expired, no GPS solution is provided at all.

Navigation Output Filters

The navigation output filters adjust the valid flag of the relevant NMEA and UBX output messages. Users of the UBX protocol have additional access to messages containing an accuracy indicator, along with the position, time and velocity solutions.

• The **pDop** and **pAcc** values: The PDOP and Position Accuracy Mask are used to determine if a position solution is marked valid in the NMEA sentences or if the UBX PosLimit flag is set. A solution is considered valid, when both PDOP and Accuracy lie below the respective limits.

• The **tDop** and **tAcc** values: The TDOP and Time Accuracy Mask are used to determine when a time pulse should be allowed. The time pulse is disabled if either TDOP or the time accuracy exceeds its respective limit. See also the TIM-TP message description.

Static Hold

The Static Hold mode allows the navigation algorithms to decrease the noise in the position output when the velocity is below a pre-defined 'Static Hold Threshold'. This reduces the position wander caused by environmental issues such as multi-path and improves position accuracy especially in stationary applications. By default, static hold mode is disabled.

If the speed goes below the defined 'Static Hold Threshold', the position is kept constant. Once the static hold mode has been entered, the position and velocity output will be kept constant, until there is evidence of movement. Such evidence can be velocity, acceleration, changes of the valid flag (e.g. position accuracy estimate exceeding the Position Accuracy Mask, see also section Navigation Output Filters), position displacement, etc.

Degraded Navigation

Degraded navigation describes all navigation modes, which use less than 4 satellites.

2D Navigation

If the receiver only has 3 satellites to calculate a position, the navigation algorithm uses a constant altitude to make up for the missing fourth satellite. When losing a satellite after a successful 3D fix (min. 4 SV available), the altitude is kept constant to the last known altitude. This is called a 2D fix.

The u-blox 5 positioning technology does not calculate any solution with a number of SVs less than 3. Only u-blox 5 Timing Receivers can calculate timing solution with only one SV when stationary.

Dead Reckoning, Extrapolating Positioning

The implemented extrapolation algorithm kicks in as soon as the receiver no longer achieves a position fix with a sufficient position accuracy or DOP value (see section Navigation Output Filters). It keeps a fix track (heading is equal to the last calculated heading) until the Dead Reckoning Timeout is reached. The position is extrapolated but it's indicated as "NoFix" (except for NMEA V2.1).

For sensor based Dead Reckoning GPS solutions, u-blox offers Dead Reckoning enabled GPS modules. They allow high accuracy position solutions for automotive applications at places with poor or no GPS coverage. This technology relies on additional inputs like a turn rate sensor (gyro) or a speed sensor (odometer or wheel tick).

Receiver Status Monitoring

Messages in this class are used to report the status of the non-GPS-specific parts of the embedded computer system.

The main purposes are

- Stack- and CPU load (Antaris 4, only)
- Hard- and Software Versions, using MON-VER

- Status of the Communications Input/Output system
- Status of various Hardware Sections with MON-HW

Input/Output system

The I/O system is a GPS-internal layer where all data input- and output capabilities (such as UART, DDC, SPI, USB) of the GPS receiver are combined. Each communications task has buffers assigned, where data is queued. For data originating at the receiver, to be communicated over one or multiple communications queues, the message MON-TXBUF can be used. This message shows the current and maximum buffer usage, as well as error conditions.

If too much data is being configured for a certain port's bandwidth (e.g. all UBX messages shall be output on a UART port with a baud rate of 9600), the buffer will fill up. Once the buffer's space is exceeded, the receiver will deactivate messages automatically.

Inbound data to the GPS receiver is placed in buffers. These buffers' usage are shown with the message MON-RXBUF. Further, as data is then decoded within the receiver (e.g. to separate UBX- and NMEA data), the MON-MSGPP can be used. This message shows, for each port and protocol, how many messages were successfully received. It also shows, for each port, how many bytes were discarded because they were not in any of the supported protocol framings.

A target in the context of the I/O system is a I/O protocol. The following table shows the target numbers used

Target Number assignment

Target #	Electrical Interface
0	DDC (I2C compatible)
1	UART 1
2	UART 2
3	USB
4	SPI
5	reserved

Protocol Number assignment

Protocol #	Protocol Name
0	UBX Protocol
1	NMEA Protocol
2	RTCM Protocol (not supported on u-blox 5)
3	RAW Protocol (not supported on u-blox 5)
47	Reserved for future use

Aiding

Introduction

The UBX Message Class AID provides all mechanisms for providing Assiste GPS Data to u-blox GPS receivers, including AssistNow Online and AssistNow Offline.

Aiding Data

Following aiding data can be submitted to the receiver:

- **Position** Position information can be submitted to the receiver using the UBX-AID-INI message. Both, ECEF X/Y/Z and latitude/longitude/height formats are supported.
- **Time** The time can either be supplied as an inexact value via the standard communication interfaces, suffering from latency depending on the baud rate, or using hardware time synchronization where an accurate time pulse is connected to an external interrupt. Both methods are supported in the UBX-AID-INI message.
- **Frequency** It is possible to supply hardware frequency aiding by connecting a continuous signal to an external interrupt using the UBX-AID-INI message.
- Orbit data Orbit data can be submitted using UBX-AID-ALM and UBX-AID-EPH.
- **Additional information** UBX-AID-HUI can be used to supply health information, UTC parameters and ionospheric data to the receiver.

Aiding Sequence

A typical aiding sequence would comprise following steps:

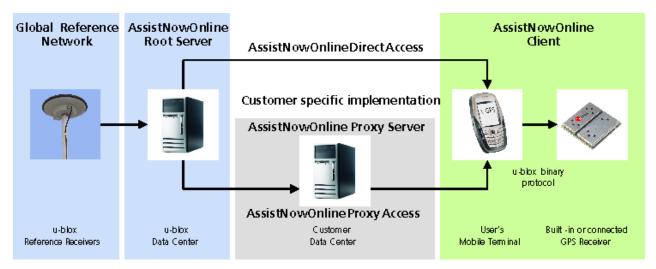

- Power-up the GPS receiver
- Send UBX-AID-INI (time, clock and position) message.
- Send UBX-AID-EPH (ephemeris) message.
- Apply optional hardware time synchronization pulse within 0.5s after (or before, depending on the configuration in UBX-AID-INI) sending the UBX-AID-INI message if hardware time synchronization is required. When sending the message before applying the pulse, make sure to allow the GPS receiver to parse and process the aiding message. The time for parsing depends on the baud rate. The processing time is 100ms maximum.
- Send optional UBX-AID-HUI (health, UTC and ionosphere parameters) message.
- Send optional UBX-AID-ALM (almanac) message.

AssistNow Online

AssistNow Online is u-blox' end-to-end Assisted GPS (A-GPS) solution that boosts GPS acquisition performance, bringing Time To First Fix (TTFF) down to seconds. The system works by accessing assistance data such as Ephemeris, Almanac and accurate time from our Global Reference Network of globally placed GPS receivers. With A-GPS, the receiver can acquire satellites and provide accurate position data instantly on demand, even under poor signal conditions.

AssistNow Online makes use of User Plane communication and open standards such as TCP/IP. Therefore, it works on all standard mobile communication networks that support Internet access, including GPRS, UMTS and Wireless LAN. No special arrangements need to be made with mobile network operators to enable AssistNow Online.

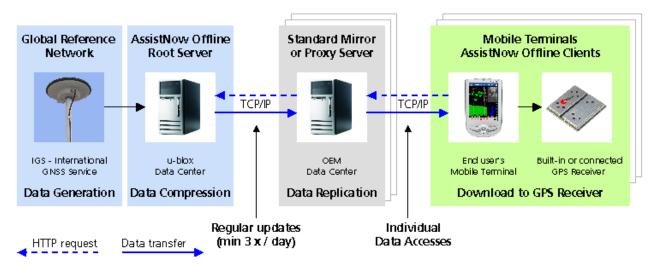

Messaging wise, AssistNow Online consists of Aiding data which deliver Position and Time UBX-AID-INI, Ephemerides UBX-AID-EPH, Almanac UBX-AID-ALM and Health/UTC/lono information UBX-AID-HUI

AssistNow Offline

AssistNow Offline is an A-GPS service that boosts GPS acquisition performance, bringing Time To First Fix (TTFF) down to seconds. Unlike AssistNow Online, this solution enables instant positioning without the need for connectivity at start-up. The system works by using AlmanacPlus (ALP) differential almanac correction data to speed up acquisition, enabling a position fix within seconds. Users access the data by means of occasional Internet downloads, at the user's convenience.

u-blox provides AlmanacPlus data files in different sizes, which contain differential almanac corrections that are valid for a period of between 1 and 14 days thereafter. Users can download correction data anytime they have an Internet connection. The GPS receiver stores the downloaded data in the non-volatile Flash EPROM. As an alternative, a host CPU may store the file, but deliver the data in pieces when requested.

AssistNow Offline works in locations without any wireless connectivity as the correction data files reside in the receiver or the host. This makes them immediately available upon start-up, eliminating connection set-up delays, download waiting times and call charges.

The simplest set-up is for GPS receivers including an internal Flash Memory where ALP data can be stored. In this case, the UBX-AID-ALP message is used.

When the GPS receiver does not contain a Flash Memory, the ALP file must be stored to the host CPU. The GPS NMEA, UBX Protocol Specification, u-blox 5 GNSS Receiver

Receiver Description GPS.G5-X-07036-D

Public Release

Page 30

receiver can the request data from the host when needed. This arrangement is implemented using the UBX-AID-ALPSRV message.

In both cases, status reporting on ALP data currently available to the GPS receiver can be taken from message AID-ALP_STAT

AssistNow Offline data are published at http://alp.u-blox.com

Please note that this functionality is only supported on u-blox 5 Firmware 4.0 and above.

Host-based AlmanacPlus Overview

All three versions of AID-ALPSRV messages are used for the case where the storage of an ALP file is not within the receiver's Flash memory, but on the host, and where the host needs to deliver data to the GPS receiver repeatedly. This allows support of the AlmanacPlus functionality for GPS receivers which do not have a Flash memory. For messaging details of an implementation where the data is to reside in the receiver's Flash memory, see UBX-AID-ALP-DESC

In the following, the GPS receiver is called the **client**, as it primarily requests data, and the host CPU where the ALP file is located in its entirety is called the **server**.

The operation is such that the client sends periodic data requests (the ALP client requests ALPSRV-REQ) to the host, and the host should answer them accordingly, as described below at ALPSRV-SRV

For this mechanism to work, the AID-ALPSRV message needs to be activated using the normal CFG-MSG commands. If it is not activated, no requests are sent out.

The client may attempt to modify the data which is stored on the server, using the ALPSRV-CLI message. The server may safely ignore such a request, in case the ALP file can not be modified. However, for improved performance for consecutive receiver restarts, it is recommended to modify the data.

Overview of the three versions of AID-ALPSRV messages

Short Name	Content	Direction
ALPSRV-REQ	ALP client requests AlmanacPlus data from server	Client -> Server
ALPSRV-SRV	ALP server sends AlmanacPlus data to client	Server -> Client
ALPSRV-CLI	ALP client sends AlmanacPlus data to server.	Client -> Server

Message specifics

The three variants of this message always have a header and variable-size data appended within the same message. The very first field, idSize gives the number of bytes where the header within the UBX payload ends and data starts.

In case of the ALP client request, the server must assemble a new message according to the AID-ALPSRV-SRV variant. The header needs to be duplicated for as many as idSize bytes. Additionally, the server needs to fill in the fileId and dataSize fields. Appended to the idSize-sized header, data must be added as requested by the client (from offset ofs, for size number of values).

Range checks

The server needs to perform an out-of-bounds check on the ofs and size fields, as the client may request data beyond the actually available data. If the client request is within the bounds of available data, the dataSize field needs to be filled in with 2 x the content of the size field (the size field is in units of 16 bits, whereas the dataSize field expects number of bytes). If the client request would request data beyond the limits of the buffer, the data should be reduced accordingly, and this actual number of bytes sent shall be indicated in the dataSize field

Changing ALP files

The server function would periodically attempt to receive new ALP data from an upstream server, as the result of an HTTP request or other means of file transfer.

In case a new file becomes available, then the server shall indicate this to the Client. This is the function of the fileId field.

The server should number ALP files it serves arbitrarily. The only requirement is that the fileId actually is changed when a new file is being served, and that it does not change as long as the same file is being changed.

If the client, as a result of a client request, receives a fileld different from the one in earlier requests' replies, it will reinitialize the ALP engine and request data anew.

Further, if the client attempts to send data to the server, using the ALPSRV-CLI method, it indicates, which fileId needs to be written. The server shall ignore that request in case the fileId numbers do not match.

Sample Code

u-blox makes available sample code, written in C language, showing a server implementation, serving ALP data from its file system to a client. Please contact your nearest u-blox Field Application engineer to receive a copy.

Please note that this functionality is only supported on u-blox 5 Firmware 4.0 and above and with special versions of Antaris 4 receivers.

Flash-based AlmanacPlus Overview

Flash-based AlmanacPlus functionality means that AlmanacPlus data is stored in the program flash memory connected to the u-blox 5 chip. The task of a server is simply to download the data from an Internet server or other sources, and then deliver the full file piece by piece to the GPS receiver. This is different to the method described in UBX-AID-ALPSRV where the file would remain within the host and the GPS receiver would request chunks from that file when needed.

The message AID-ALP exists in several variants, combining all functionality needed to download data and report status within one Class/Message ID.

Download Procedure

The following steps are a typical sequence for downloading an ALP file to the receiver:

• The server downloads a copy of a current ALP file, and stores it locally

- It sends the first N bytes from that file, using the AID-ALP-TX message
- The server awaits a AID-ALP-ACK or AID-ALP-NAK message.
- If can then continue, sending the next N bytes if the message was acknowledged.
- Once all data has been transferred, or a NAK has been received, the server sends an AID-ALP-STOP message

Please note that

- N should not be larger than ~700 bytes (due to the input buffers on the RS232/USB lines). Smaller values of N might improve reliability
- N must be a multiple of 2.
- There is no re-send mechanism. If a NAK message is received, the full downloading process must be restarted.
- There is no explicit checksum, but an implicit one, as the ALP file already includes a checksum to verify consistency

Overview of the different versions of AID-ALP messages

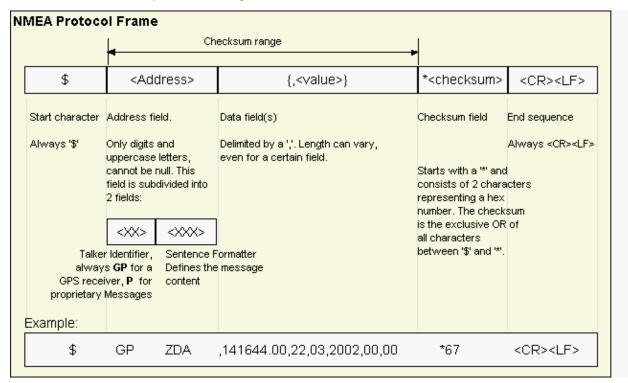

Short Name	Content	Direction
AID-ALP-TX	ALP server sends Data to client	Server -> Client
AID-ALP-STOP	ALP server terminates a transfer sequence	Server -> Client
AID-ALP-ACK	ALP client acknowledges successful receipt of data.	Client -> Server
AID-ALP-NAK	ALP client indicates a failed reception of data	Client -> Server
AID-ALP-STAT	ALP client reports status of the ALP data stored in flash memory	Client -> Server

NMEA Protocol

Protocol Overview

NMEA messages sent by the GPS receiver are based on NMEA 0183 Version 2.3. The following picture shows the structure of a NMEA protocol message.

For further information on the NMEA Standard please refer to *NMEA 0183 Standard For Interfacing Marine Electronic Devices*, Version 2.30, March 1, 1998. See http://www.nmea.org/ for ordering instructions.

The NMEA standard allows for proprietary, manufacturer-specific messages to be added. These shall be marked with a manufacturer mnemonic. The mnemonic assigned to u-blox is UBX and is used for all non-standard messages. These proprietary NMEA messages therefore have the address field set to PUBX. The first data field in a PUBX message identifies the message number with two digits.

Latitude and Longitude Format

According to the NMEA Standard, Latitude and Longitude are output in the format Degrees, Minutes and (Decimal) Fractions of Minutes. To convert to Degrees and Fractions of Degrees, or Degrees, Minutes, Seconds and Fractions of seconds, the 'Minutes' and 'Fractional Minutes' parts need to be converted. In other words: If the GPS Receiver reports a Latitude of 4717.112671 North and Longitude of 00833.914843 East, this is

Latitude 47 Degrees, 17.112671 Minutes

Longitude 8 Degrees, 33.914843 Minutes

or

Latitude 47 Degrees, 17 Minutes, 6.76026 Seconds Longitude 8 Degrees, 33 Minutes, 54.89058 Seconds

or

Latitude 47.28521118 Degrees Longitude 8.56524738 Degrees

Position Fix Flags in NMEA Mode

The following list shows how u-blox implements the NMEA protocol, and the conditions determining how flags are set in version 2.3 and above.

NMEA Message: Field	No position fix (at	Valid position fix,	Dead reckoning	EKF (only on DR	2D position fix	3D position fix	combined GPS/EKF	
	power-up, after	but user limits	(linear	receivers)			position fix (only on DR	
	losing satellite lock)	exceeded	extrapolation)				receivers)	
GLL, RMC: Status	V	V	V	А	А	А	А	
	A=Data VALID, V=Data Invalid (Navigation Receiver Warning)							
GGA: Quality Indicator	0	0	6	6	1/2	1/2	1/2	
	0=Fix not available/in	Fix not available/invalid, 1=GPS SPS Mode, Fix valid, 2=Differential GPS, SPS Mode, Fix Valid, 6=Estimated/Dead Reckoning						
GSA: Nav Mode	1	1	2	2	2	3	3	
	1=Fix Not available, 2	?=2D Fix, 3=3D Fix						
GLL, RMC, VTG: Mode	N	N	Е	Е	A/D	A/D	A/D	
Indicator								
	N=No Fix, A=Autonomous GNSS Fix, D=Differential GNSS Fix, E=Estimated/Dead Reckoning Fix							
UBX GPSFixOK	0	0	0	1	1	1	1	
UBX GPSFix	0	>1	1	1	2	3	4	

The following list shows how u-blox implements the NMEA protocol, and the conditions determining how flags are set in version 2.2 and below.

NMEA Message: Field	No position fix (at	Valid position fix,	Dead reckoning	EKF (only on DR	2D position fix	3D position fix	combined GPS/EKF
	power-up, after	but user limits	(linear	receivers)			position fix (only on DR
	losing satellite lock	exceeded	extrapolation)				receivers)
GLL, RMC: Status	V	V	А	А	А	А	А
	A=Data VALID, V=Data Invalid (Navigation Receiver Warning)						
GGA: Quality Indicator	0	0	1	1	1/2	1/2	1/2
	0=Fix not available/invalid, 1=GPS SPS Mode, Fix valid, 2=Differential GPS, SPS Mode, Fix Valid						
GSA: Nav Mode	1	1	2	2	2	3	3
	1=Fix Not available, 2=2D Fix, 3=3D Fix						
GLL, RMC, VTG: Mode Indicator. This field is not output by this NMEA version.							
UBX GPSFixOK	0	0	0	1	1	1	1
UBX GPSFix	0	>1	1	1	2	3	4

By default the receiver will not output invalid data. In such cases, it will output empty fields.

• A valid position fix is reported as follows:

\$GPGLL,4717.11634,N,00833.91297,E,124923.00,A,A*6E

• An invalid position fix (but time valid) is reported as follows:

\$GPGLL,,,,,124924.00,V,N*42

• If Time is unknown (e.g. during a cold-start):

\$GPGLL,,,,,,V,N*64

In Antaris firmware versions older than 3.0, the receiver did output invalid data and marked it with the 'Invalid/Valid' Flags. If required, this function can still be enabled in later firmware versions, using the UBX protocol message CFG-NMEA.

NMEA Messages Overview

When configuring NMEA messages using the UBX protocol message CFG-MSG, the Class/lds shown in the table shall be used.

Page	Mnemonic	Cls/ID	Description	
	NMEA Proprietary Messages		Proprietary Messages	
52	UBX,00	0xF1 0x00	Lat/Long Position Data	
54	UBX,03	0xF1 0x03	Satellite Status	
56	UBX,04	0xF1 0x04	Time of Day and Clock Information	
58	UBX,40	0xF1 0x40	Set NMEA message output rate	
59	UBX,41	0xF1 0x41	Set Protocols and Baudrate	
57	UBX	0xF1 0x40	Poll a PUBX message	
	NMEA Standard Mes	ssages	Standard Messages	
49	DTM	0xF0 0x0A	Datum Reference	
48	GBS	0xF0 0x09	GNSS Satellite Fault Detection

Standard Messages

Standard Messages: i.e. Messages as defined in the NMEA Standard.

GGA

Message	GGA	GGA						
Description	Global positio	Global positioning system fix data						
Туре	Output Messag	Output Message						
Comment	The output of	The output of this message is dependent on the currently selected datum (Default:						
	WGS84)	WGS84)						
	Time and positi	Time and position, together with GPS fixing related data (number of satellites in use, and						
	the resulting HI	the resulting HDOP, age of differential data if in use, etc.).						
	ID for CFG-MSG	ID for CFG-MSG Number of fields						
Message Info	0xF0 0x00	17						

Message Structure:

Example:

\$GPGGA,092725.00,4717.11399,N,00833.91590,E,1,8,1.01,499.6,M,48.0,M,,0*5B

Field	Example	Format	Name	Unit	Description
No.					
0	\$GPGGA	string	\$GPGGA	-	Message ID, GGA protocol header
1	092725.00	hhmmss.sss	hhmmss.	-	UTC Time, Current time
			ss		
2	4717.11399	ddmm.mmmm	Latitude	-	Latitude, Degrees + minutes, see Format description
3	N	character	N	-	N/S Indicator, N=north or S=south
4	00833.91590	dddmm.	Longitud	-	Longitude, Degrees + minutes, see Format
		mmmm	е		description
5	Е	character	E	-	E/W indicator, E=east or W=west
6	1	digit	FS	-	Position Fix Status Indicator, See Table below and
					Position Fix Flags description
7	8	numeric	NoSV	-	Satellites Used, Range 0 to 12
8	1.01	numeric	HDOP	-	HDOP, Horizontal Dilution of Precision
9	499.6	numeric	msl	m	MSL Altitude
10	M	character	uMsl	-	Units, Meters (fixed field)
11	48.0	numeric	Altref	m	Geoid Separation
12	M	character	uSep	-	Units, Meters (fixed field)
13	-	numeric	DiffAge	S	Age of Differential Corrections, Blank (Null) fields
					when DGPS is not used
14	0	numeric	DiffStat	-	Diff. Reference Station ID
			ion		
15	*5B	hexadecimal	cs	-	Checksum
16	-	character	<cr><lf></lf></cr>	-	Carriage Return and Line Feed

GBS

Message	GBS						
Description	GNSS Satellite Fault Detection						
Туре	Output Message						
Comment	This message outputs the results of the Receiver Autonomous Integrity Monitoring Algorithm (RAIM). • The fields errlat, errlon and erralt output the standard deviation of the position calculation, using all satellites which pass the RAIM test successfully. • The fields errlat, errlon and erralt are only output if the RAIM process passed successfully (i.e. no or successful Edits happened). These fields are never output if 4 or fewer satellites are used for the navigation calculation (because - in this case - integrity can not be determined by the receiver autonomously) • The fields prob, bias and stdev are only output if at least one satellite failed in the RAIM test. If more than one satellites fail the RAIM test, only the information for the						
	ID for CFG-MSG Number of fields						
Message Info	0xF0 0x09 11						

Message Structure:

\$GPGBS,hhmmss.ss,errlat,errlon,erralt,svid,prob,bias,stddev*cs<CR><LF>

Example:

\$GPGBS,235503.00,1.6,1.4,3.2,,,,*40

UBX Protocol

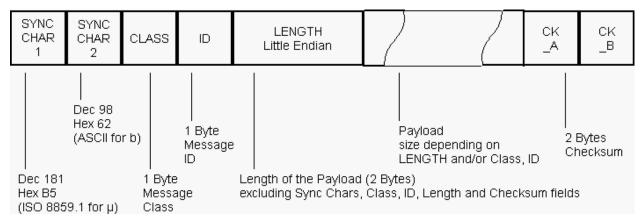

UBX Protocol Key Features

u-blox GPS receivers use a u-blox proprietary protocol to transmit GPS data to a host computer using asynchronous RS232 ports. This protocol has the following key features:

- Compact uses 8 Bit Binary Data.
- Checksum Protected uses a low-overhead checksum algorithm
- Modular uses a 2-stage message identifier (Class- and Message ID)

UBX Packet Structure

A basic UBX Packet looks as follows:

- Every Message starts with 2 Bytes: 0xB5 0x62
- A 1 Byte Class Field follows. The Class defines the basic subset of the message
- A 1 Byte ID Field defines the message that is to follow
- A 2 Byte Length Field is following. Length is defined as being the length of the payload, only. It does not
 include Sync Chars, Length Field, Class, ID or CRC fields. The number format of the length field is an
 unsigned 16-Bit integer in Little Endian Format.
- The Payload is a variable length field.
- CK_A and CK_B is a 16 Bit checksum whose calculation is defined below.

UBX Class IDs

A Class is a grouping of messages which are related to each other. The following table gives the short names, description and Class ID Definitions.

Name	Class	Description
NAV	0x01	Navigation Results: Position, Speed, Time, Acc, Heading, DOP, SVs used
RXM	0x02	Receiver Manager Messages: Satellite Status, RTC Status
INF	0x04	Information Messages: Printf-Style Messages, with IDs such as Error, Warning, Notice
ACK	0x05	Ack/Nack Messages: as replies to CFG Input Messages
CFG	0x06	Configuration Input Messages: Set Dynamic Model, Set DOP Mask, Set Baud Rate, etc.
MON	0x0A	Monitoring Messages: Comunication Status, CPU Load, Stack Usage, Task Status

UBX Class IDs continued

Name	Class	Description
AID	0x0B	AssistNow Aiding Messages: Ephemeris, Almanac, other A-GPS data input
TIM	0x0D	Timing Messages: Timepulse Output, Timemark Results

All remaining class IDs are reserved.

UBX Payload Definition Rules

Structure Packing

Values are placed in an order that structure packing is not a problem. This means that 2Byte values shall start on offsets which are a multiple of 2, 4-byte values shall start at a multiple of 4, and so on. This can easily be achieved by placing the largest values first in the Message payload (e.g. R8), and ending with the smallest (i.e. one-byters such as U1) values.

Message Naming

Referring to messages is done by adding the class name and a dash in front of the message name. For example, the ECEF-Message is referred to as NAV-POSECEF. Referring to values is done by adding a dash and the name, e.g. NAV-POSECEF-X

Number Formats

All multi-byte values are ordered in Little Endian format, unless otherwise indicated.

All floating point values are transmitted in IEEE754 single or double precision. A technical description of the IEEE754 format can be found in the AnswerBook from the ADS1.x toolkit.

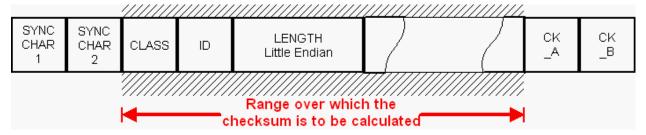

The following table gives information about the various values:

		1		N 4: /N 4	Danal stine
Short	Type	Size (Bytes)	Comment	Min/Max	Resolution
U1	Unsigned Char	1		0255	1
11	Signed Char	1	2's complement	-128127	1
X1	Bitfield	1		n/a	n/a
U2	Unsigned Short	2		065535	1
12	Signed Short	2	2's complement	-3276832767	1
X2	Bitfield	2		n/a	n/a
U4	Unsigned Long	4		04'294'967'295	1
14	Signed Long	4	2's complement	-2'147'483'648	1
				2'147'483'647	
X4	Bitfield	4		n/a	n/a
R4	IEEE 754 Single Precision	4		-1*2^+127	~ Value * 2^-24
				2^+127	
R8	IEEE 754 Double Precision	8		-1*2^+1023	~ Value * 2^-53
				2^+1023	
СН	ASCII / ISO 8859.1 Encoding	1			

UBX Checksum

The checksum is calculated over the packet, starting and including the CLASS field, up until, but excluding, the Checksum Field:

The checksum algorithm used is the 8-Bit Fletcher Algorithm, which is used in the TCP standard (<u>RFC 1145</u>). This algorithm works as follows:

Buffer[N] contains the data over which the checksum is to be calculated.

The two CK_ values are 8-Bit unsigned integers, only! If implementing with larger-sized integer values, make sure to mask both CK_A and CK_B with 0xFF after both operations in the loop.

```
CK_A = 0, CK_B = 0
For(I=0;I<N;I++)
{
    CK_A = CK_A + Buffer[I]
    CK_B = CK_B + CK_A
}</pre>
```

After the loop, the two U1 values contain the checksum, transmitted at the end of the packet.

UBX Message Flow

There are certain features associated with the messages being sent back and forth:

Acknowledgement

When messages from the Class CFG are sent to the receiver, the receiver will send an Acknowledge (ACK-ACK) or a Not Acknowledge (ACK-NAK) message back to the sender, depending on whether or not the message was processed correctly.

There is no ACK/NAK mechanism for message poll requests outside Class CFG.

Polling Mechanism

All messages that are output by the receiver in a periodic manner (i.e. Messages in Classes MON, NAV and RXM) can also be polled.

There is not a single specific message which polls any other message. The UBX protocol was designed such, that when sending a message with no payload (or just a single parameter which identifies the poll request) the message is polled.

Bitfield age

This Graphic explains the bits of age

Name	Description
almAge	Age of ALM in days offset by 4
	i.e. the reference time may be in the future:
	ageOfAlm = (age & 0x0f) - 4
ephAge	Age of EPH in hours offset by 4.
	i.e. the reference time may be in the future:
	ageOfEph = ((age & 0xf0) >> 4) - 4

INF (0x04)

Information Messages: i.e. Printf-Style Messages, with IDs such as Error, Warning, Notice.

The INF Class is basically an output class that allows the firmware and application code to output strings with a printf-style call. All INF messages have an associated type to indicate the kind of message.

INF-ERROR (0x04 0x00)

ASCII String output, indicating an error

Message		INF	NF-ERROR									
Description		AS	ASCII String output, indicating an error									
Туре												
Comment		Thi	s message	has a variab	le lengt	h payloa	d, representing an	ASCII str	ring.

ACK (0x05)

Ack/Nack Messages: i.e. as replies to CFG Input Messages.

Messages in this class are sent as a result of a CFG message being received, decoded and processed by the receiver.

ACK-NAK (0x05 0x00)

Message Not-Acknowledged

Message		AC	CK-NAK										
Description		Me	Message Not-Acknowledged										
Туре		Ans	nswer

CFG (0x06)

Configuration Input Messages: i.e. Set Dynamic Model, Set DOP Mask, Set Baud Rate, etc..

The CFG Class can be used to configure the receiver and read out current configuration values. Any messages in Class CFG sent to the receiver are acknowledged (with Message ACK-ACK) if processed successfully, and rejected (with Message ACK-NAK) if processing the message failed.

ALP file data transfer to the receiver

Message	,	AID	-ALP						
Description		ALF	file dat	a transfer to	the re	eceiver			
Туре		Inpı	ut messag	ge					
This message is used to transfer a chunk of data from the AlmanacPlus file to the receiver upon reception of this message, the receiver will write the payload data to its internal non-volatile memory, eventually also erasing that part of the memory first. Make sure the payload size is even sized (i.e. always a multiple of 2). Do not use payloads larger the 700 bytes, as this would exceed the receiver's internal buffering capabilities. The receiver will (not-) acknowledge this message using the message alternatives given below. The households are considered to the receiver will write the payload data to its internal non-volatile memory, eventually also erasing that part of the memory first. Make sure the payload size is even sized (i.e. always a multiple of 2). Do not use payloads larger the payload size is even sized (i.e. always a multiple of 2).						a to its internal Make sure that oads larger than ies. The receiver

Mark end of data transfer

Message		AID	D-ALP								
Description		Ма	rk end o	f data trans	fer						
Туре		Inp	put message								
Comment		ope rece me:	This message is used to indicate that all chunks have been transferred, and normal receiver operation can resume. Upon reception of this message, the receiver will verify all chunks received so far, and enable AssistNow Offline and GPS receiver operation if successful. This message could also be sent to cancel an incomplete download.

u-blox 5 Default Settings

The default settings listed in this section apply to u-blox 5 ROM-based receivers with ROM version 4.0. These values assume that the default levels of the configuration pins have been left unchanged. Default settings are dependent on the configuration pin settings, for information regarding these settings, consult the applicable Data Sheet.

Antenna Supervisor Settings (UBX-CFG-ANT)

For parameter and protocol description see section UBX-CFG-ANT.

Antenna Settings

Parameter	Default Setting	Unit
Enable Control Signal	Enabled	
Enable Short Circuit Detection	Enabled	
Enable Short Circuit Power Down logic	Enabled	
Enable Automatic Short Circuit Recovery logic	Enabled	
Enable Open Circuit Detection	Disabled	

Datum Settings (UBX-CFG-DAT)

For parameter and protocol description see section UBX-CFG-DAT.

Datum Default Settings

Parameter	Default Setting	Unit
Datum	0 – WGS84	

Navigation Settings (UBX-CFG-NAV5)

For parameter and protocol description see section UBX-CFG-NAV5.

Navigation Default Settings

Parameter	Default Setting	Unit
Dynamic Platform Model	0 – Portable	
Fix Mode	Auto 2D/3D	#
Fixed Altitude	N/A	m
Fixed Altitude Variance	N/A	m^2
Min SV Elevation	5	deg
DR Timeout	0	S
PDOP Mask	25	-
TDOP Mask	25	-
P Accuracy	100	m
T Accuracy	300	m
Static Hold Threshold	0.00	m/s

Output Rates (UBX-CFG-RATE)

For parameter and protocol description see section UBX-CFG-RATE.

Output Rate Default Settings

Parameter	Default Setting	Unit
Time Source	1 – GPS time	
Measurement Period	1000	ms
Measurement Rate	1	Cycles

SBAS Configuration (UBX-CFG-SBAS)

For parameter and protocol description see section UBX-CFG-SBAS.

SBAS Configuration Default Settings

Parameter	Default Setting	Unit
SBAS Subsystem	Enabled	
Allow test mode usage	Disabled	
Ranging (Use SBAS for navigation)	Enabled	
Apply SBAS Correction Data	Enabled	
Apply integrity information	Disabled	
Number of search channels	3	
PRN Codes	120, 122, 124, 126-127, 129, 131, 134-135, 137-138	

Port Setting (UBX-CFG-PRT)

For parameter and protocol description see section UBX-CFG-PRT.

Port Default Settings

Parameter	Default Setting	Unit
DDC/I2C (Target0)		
Protocol in	0+1 – UBX+NMEA	
Protocol out	0+1 – UBX+NMEA	
USART1 (Target1)		
Protocol in	0+1 – UBX+NMEA	
Protocol out	0+1 – UBX+NMEA	
Baudrate	9600	baud
USART2 (Target2)		
Protocol in	None	
Protocol out	None	
Baudrate	9600	baud
USB (Target3)		
Protocol in	0+1 – UBX+NMEA	
Protocol out	0+1 – UBX+NMEA	
SPI (Target4)		
Protocol in	0+1 – UBX+NMEA	
Protocol out	0+1 – UBX+NMEA	

Port Setting (UBX-CFG-USB)

For parameter and protocol description see section UBX-CFG-USB.

USB default settings

Parameter	Default Setting	Unit
Power Mode		
Power Mode	Bus powered	
Bus Current required	120	mΑ

Message Settings (UBX-CFG-MSG)

For parameter and protocol description see section UBX-CFG-MSG.

Enabled output messages

Message	Туре	All Targets
NMEA - GGA	Out	1
NMEA - GLL	Out	1
NMEA - GSA	Out	1
NMEA - GSV	Out	1
NMEA - RMC	Out	1
NMEA - VTG	Out	1

NMEA Protocol Settings (UBX-CFG-NMEA)

For parameter and protocol description see section UBX-CFG-NMEA.

NMEA Protocol Default Settings

Parameter	Default Setting	Unit
Enable position output even for invalid fixes	Disabled	
Enable position even for masked fixes	Disabled	
Enable time output even for invalid times	Disabled	
Enable time output even for invalid dates	Disabled	
Version	2.3	
Compatibility Mode	Disabled	
Consideration Mode	Enabled	
Number of SV	Unlimited	

INF Messages Settings (UBX–CFG–INF)

For parameter and protocol description see section UBX-CFG-INF.

NMEA default enabled INF msg

Message	Туре	All Targets	Range/Remark
INF-Error	Out	1	In NMEA Protocol only (GPTXT)
INF-Warning	Out	1	In NMEA Protocol only (GPTXT)
INF-Notice	Out	1	In NMEA Protocol only (GPTXT)
INF-Test	Out		

NMEA default enabled INF msg continued

Message	Туре	All Targets	Range/Remark
INF-Debug	Out
